A Simple Framework Appendix

A.1 Additional factor of production and labor-saving development

In this section, I introduce additional theoretical results by introducing an additional fixed factor of production, denoted land T . The purpose here is to discuss the additional theoretical characterization that the presence of the fixed factor can produce. Then, I discuss how much this addition is relevant to the baseline setting in the paper.

Consider a CES production function for agriculture with three factors of production:

$$Y = [\rho(Z_L L)^{\frac{\sigma-1}{\sigma}} + (1-\rho)(Z_K K)^{\frac{\sigma-1}{\sigma}}]^{\frac{\gamma\sigma}{\sigma-1}} \sigma T^{1-\gamma}, \quad (\text{OA1})$$

where Z_L and Z_K represent factor-augmenting technologies as in the main text. Industry superscript for agriculture is dropped. The new parameter $\gamma \in (0, 1)$ measures the labor-capital composite share of production in agriculture. Hence, agriculture exhibits decreasing returns to labor and capital when land is held constant.

By following Acemoglu (2010), I define the strong labor-saving economic development:

Definition 1 (Labor-saving economic development). *Economic development is **strongly labor-saving** if the marginal product of labor decreases when the level of technology or capital stock increases. In particular,*

$$\frac{\partial(\partial Y/\partial L)}{\partial Z} < 0 \quad \text{or} \quad \frac{\partial(\partial Y/\partial L)}{\partial K} < 0. \quad (\text{OA2})$$

Given the stated production function, whether the development is strongly labor-saving depends on the values of parameters (Acemoglu, 2010). For technology to be strongly labor-saving, three conditions are needed: (1) $\gamma < 1$; (2) $\sigma > 1$; and (3) $1 - \gamma > 1/\sigma$ with capital augmenting technology. The opposite parametric restriction on (3) should hold with labor-augmenting technology. Given $\sigma > 1$ estimated in the literature (Herrendorf et al., 2015; Boppart et al., 2023), I focus on the former case. The condition suggests that decreasing return to scale of labor-capital composite and high elasticity of substitution between the two are required for capital augmenting technology or capital accumulation to yield strongly labor-saving development.

With the value of $\sigma = 1.58$ (Herrendorf et al., 2015), the land share of production should be greater than 0.63 to satisfy the third condition. However, labor share in agriculture is calculated to be 0.34 using the long-run averages of factor payment share to labor using *USDA Farm Income and Wealth Statistics* (Yang, 2024). Hence, agriculture is unlikely to have been strongly labor-saving during the 20th-century United States setting within the reasonable range of parameter values.

A.2 Proof and discussion for Predictions

Predictions 1 and 2.

The proofs for Predictions 1 and 2 follow Proposition 1 of Alvarez-Cuadrado et al. (2017). This subsection outlines the key ideas of the proof. Let consumption share on non-agriculture (“m”) be $0 < \gamma < 1$ in the Cobb-Douglas consumption allocation. Then, with total output Y and price index P , the economic allocation is given as:

$$Y^a = (1 - \gamma) \frac{P}{p^a} Y \quad \text{and} \quad Y^m = \gamma \frac{P}{p^m} Y, \quad (\text{OA3})$$

where the subscript indexes sector. The price index P is normalized to one:

$$P = p^a \frac{Y^a}{Y} + p^m \frac{Y^m}{Y} = (1 - \gamma) p^a + \gamma p^m \equiv 1. \quad (\text{OA4})$$

At any point in time, free mobility of capital and labor implies the equalization of the marginal value products across sectors within the region:

$$p^a \rho \left(\frac{Y^a}{K^a} \right)^{1/\sigma^a} = p^m \rho \left(\frac{Y^m}{K^m} \right)^{1/\sigma^m} = R, \quad (\text{OA5})$$

$$p^a (1 - \rho) \left(\frac{Y^a}{K^a} \right)^{1/\sigma^a} A^{\frac{\sigma^a - 1}{\sigma^a}} = p^m (1 - \rho) \left(\frac{Y^m}{L^m} \right)^{1/\sigma^m} A^{\frac{\sigma^m - 1}{\sigma^m}} = w. \quad (\text{OA6})$$

In order to obtain analytical results, I restrict non-agriculture to Cobb-Douglas by setting $\sigma_A = \sigma > 1$ and $\sigma_M = 1$. By combining Equations (OA3), (OA4), (OA5), and (OA6), the share of labor in agriculture, λ , and capital, κ , are each governed by the equilibrium relationships:

$$\lambda - (1 - \lambda)^{1/\sigma} A^{\frac{1-\sigma}{\sigma}} K^{\frac{\sigma-1}{\sigma}} \frac{\kappa}{(1 - \kappa)^{1/\sigma}} = 0, \quad (\text{OA7})$$

$$\kappa - (1 - \kappa)^{1-\sigma} \frac{\gamma}{1 - \gamma} \left(\frac{Y^a}{K} \right)^{\frac{\sigma-1}{\sigma}} = 0, \quad (\text{OA8})$$

where

$$\left(\frac{Y^a}{K} \right)^{\frac{\sigma-1}{\sigma}} = (1 - \alpha) \left(\frac{(1 - \lambda)A}{K} \right)^{\frac{\sigma-1}{\sigma}} + \alpha (1 - \kappa)^{\frac{\sigma-1}{\sigma}}.$$

Combining Equations (OA7) and (OA8) yields the following relationship between the shares:

$$\lambda = \lambda(\kappa) = \frac{\gamma(1 - \alpha)\kappa}{\kappa - \alpha\gamma} \quad \text{with} \quad \frac{d\lambda}{d\kappa} = - \left(\frac{\alpha}{1 - \alpha} \right) \left(\frac{\lambda(\kappa)}{\kappa} \right) < 0, \quad (\text{OA9})$$

which states that the share of labor and capital allocated to agriculture exhibits the opposite sign

from a common shock.

Finally, manipulating Equations (OA7) and (OA9) and taking logarithms gives:

$$\frac{1-\sigma}{\sigma} \ln K = \frac{1}{\sigma} \ln(1-\lambda(\kappa)) - \ln(\lambda(\kappa)) + \frac{1-\sigma}{\sigma} \ln A + \ln \kappa - \frac{1}{\sigma} \ln(1-\kappa). \quad (\text{OA10})$$

The result for the capital share is obtained by totally differentiating Equation (OA10):

$$\frac{\partial \kappa}{\partial k} = \frac{(1-\sigma)}{\sigma G(\kappa)k} > 0,$$

where $G(\kappa) \equiv \left[\frac{1}{\sigma(1-\lambda(\kappa))} + \frac{1}{\lambda(\kappa)} \right] \left(\frac{\lambda(\kappa)}{\kappa} \right) \left(\frac{\alpha}{1-\alpha} \right) + \left[\frac{1}{\kappa} + \frac{1}{\sigma(1-\kappa)} \right]$. Hence, the capital share on agriculture rises as the regional capital-to-labor ratio, k , increases. The result for the labor share follows from Equation (OA9).

Prediction 3.

The classical proof using factor price equalization is first explained below. Consider unit costs and production constraints using input coefficients:

$$\begin{aligned} a_L^a w + a_K^a r &= p^a, \\ a_L^m w + a_K^m r &= p^m, \end{aligned} \quad (\text{OA11})$$

and

$$\begin{aligned} a_L^a A + a_K^a M &= L, \\ a_L^m A + a_K^m M &= K, \end{aligned} \quad (\text{OA12})$$

where the first two conditions are derived from the zero profit condition, and the last two are derived from the full employment assumption. The coefficient a_k^s is a derivative of unit cost functions with respect to factor prices and measures factor content of k on industry s at the initial equilibrium. The agriculture is more capital intensive if

$$\frac{a_K^a}{a_L^a} > \frac{a_K^m}{a_L^m}. \quad (\text{OA13})$$

The following derivation relies on the assumption that factor intensity is not reversed.

By taking derivatives of Equation (OA12) with respect to labor,

$$\begin{aligned} a_L^a \frac{\partial A}{\partial L} + a_K^a \frac{\partial M}{\partial L} &= 1, \\ a_L^m \frac{\partial A}{\partial L} + a_K^m \frac{\partial M}{\partial L} &= 0, \end{aligned} \tag{OA14}$$

and applying the Cramer's rule yields:

$$\begin{aligned} \frac{\partial A}{\partial L} &= \frac{a_K^m}{a_L^a a_K^m - a_L^m a_K^a}, \\ \frac{\partial M}{\partial L} &= \frac{a_K^a}{a_L^a a_K^m - a_L^m a_K^a}. \end{aligned} \tag{OA15}$$

Under the assumption that agriculture is labor intensive and the South is labor abundant, $\frac{\partial A}{\partial L} > 0$ and $\frac{\partial M}{\partial L} < 0$ should hold from Equation (OA15). In other words, out-migration contracts agriculture and expands non-agriculture production. Note that Equation (OA14) uses factor price equalization result where factor prices only depend on output prices, which is assumed to be constant. As long as the number of goods and the number of factors are equal, the same logic can be applied to an arbitrary number of goods and factors where an increase in endowment of one factor decreases the output of one good and increases the output of the others (Jones and Scheinkman, 1977).

Nonetheless, the factor price equalization is unlikely to hold in the real world. Romalis (2004), instead, lays out a model of two factors of production, multiple countries with continuous industries that differ in factor intensity. He derives the quasi-Rybczynski Theorem without the factor price equalization but with the introduction of trade costs and monopolistic competition, allowing regional differences in production costs. The quantitative model is closer to his formulation by incorporating the CES cost function into the Eaton and Kortum (2002) setting.

A.3 Further division within non-agriculture.

Here, I point out that the out-migration would not necessarily have affected every corner of the economy by conceptualizing a sector that is not covered by the simple framework. I introduce a third sector that only uses labor and is nontradable, denoting it as a human capital-intensive non-agriculture task.

$$\text{human capital-intensive non-agricultural task: } Y^S = Z_L^S L^S,$$

which can be derived by setting $\rho \rightarrow 1$ and $\sigma \rightarrow 0$.

The division between the baseline non-agriculture and the human capital-intensive task resem-

bles the classification between manufacturing and services. However, the distinction here aims to highlight the differences arising from factor usage rather than the consumption characteristics of industries.¹ In real life, both manufacturing and services use labor and capital. Instead, depending on their primary factor usage, subsectors in non-agriculture can be classified as human capital-intensive. For instance, retail and wholesale are closer to the baseline non-agriculture that uses both labor and capital, while business services and education are better described as human capital-intensive because they primarily rely on (skilled) human labor.

How are the predictions affected by the introduction of the third sector? Since it does not use capital, the introduction of the new sector does not affect the closed-economy results of capital reallocation. The labor share in the human capital-intensive sector is not directly affected, either.² In other words, this component of the economy represents the portion that is expected to be not much affected by the changes from the Great Migration. If they are tradable, they would experience a decrease in comparative advantage as it has the highest share of labor.

B Data Appendix

B.1 Dependent variables

Agriculture

Unless mentioned otherwise, agriculture variables are from Agriculture Census compiled by Haines et al. (2018).

- Agricultural employment: Number of employed in agriculture. 1940-2012. The values between 1940 and 1997 are from HDES (Haines et al., 2010) (“Number of employed in agriculture”), while the values between 2002 and 2012 are from Census Bureau (2023b) (“Farm employment”).
- Number of farms: Farms, number. 1940-2012.
- Acres in farmland: Land in farms, acres, including cropland, pasture, and woodland. 1940-2012.
- Number of tractors: Tractors, number. 1940-2012.

¹This approach is in line with the value-added classification of industries, compared to the final expenditure classification (Herrendorf et al., 2013).

²The general equilibrium effects through changes in income and relative changes in factor prices are relatively small for a reasonable range of parameter values, and hence, the main implication in terms of labor reallocation would be maintained.

- Number of combines: Grain combines, number. 1950-2010.
- Farm output: Crop revenue and animal revenue. The sum of the value of all crops sold and the value of all animal products sold and animals sold. 1940-2012.
- Farm value per acre: The value of farmland, including buildings and improvements attached to the land (excluding implements and machinery). 1940-2012.

Manufacturing

The values for 1940-2000 (until 2002) are from HDES, while the values for 2010 (2007 and 2012) are from Census Bureau (2013), using “NAICS Sector 31- Manufacturing.”

- Manufacturing employment: Manufacturing employees. 1940-2012.
- Number of establishment: Number of manufacturing establishments. 1940-2012.
- Capital spending: Manufacturing capital spending. 1954, 1958, 1963, 1967, 1972, 1982, 2002, 2007, and 2012.
- Manufacturing Value added: Manufacturing value added. 1940-2012.
- Manufacturing Annual payroll: Total manufacturing wages (workers). 1940-2012.

Services

Unless mentioned otherwise, the values for 1940-2000 (until 2002) are from HDES, while the values for 2010 (2007 and 2012) are from Census Bureau (2013), using “NAICS Sector 42- Wholesale Trade” and “Retail Trade (NAICS Sector 44).”

- Wholesale employment: Average annual employees of wholesale stores or paid employment in the week including March 12. 1940-2012.
- Wholesale establishments: Number of wholesale establishments. 1940-2012.
- Wholesale sales: Total sales in wholesale establishments. 1940-2012.
- Wholesale annual payroll: Total payroll in wholesale establishments. 1940-2012.
- Retail employment: Average annual employees in retail stores or paid employment in the week including March 12. 1940-2012.
- Retail establishments: Number of retail establishments. 1940-2012.
- Retail sales: Total sales in retail stores. 1940-2012.

- Retail annual payroll: Total payroll in retail stores. 1940-2012.
- Consumer services employment: HDES does not report detailed information on the services sector. Instead, I use the County Business Patterns. Wholesale Trade (NAICS 42), Retail Trade (NAICS 44-45), Transportation and Warehousing (NAICS 48-49), Finance and Insurance (NAICS 52), Real Estate and Rental and Leasing (NAICS 53), Health Care and Social Assistance (NAICS 62), Arts, Entertainment, and Recreation (NAICS 71), Accommodation and Food Services (NAICS 72). Educational Services (NAICS 61) are excluded and examined separately. 1980-2010. Corresponding industry employments in 1940 and 1950 from the full count population Census (using “IND1950”) are used as the base. Source: Census Bureau (2023a) and Ruggles et al. (2024).
- Producer services employment: Information (NAICS 51), Professional, Scientific, and Technical Services (NAICS 54), Management of Companies and Enterprises (NAICS 55). 1980-2010. Corresponding industry employments in 1940 and 1950 from the full count population Census (using “IND1950”) are used as the base. Source: Census Bureau (2023a) and Ruggles et al. (2024).

Education

- Median school year: Median years of schooling for persons over 25. For 1940, I take an average value of males’ and females’ median school year, as they are reported separately. 1940, 1950, 1960, and 1970. Source: HDES.
- Share high school: Share of persons over 25 with 1-3 years of high school. 1940-2000. Source: HDES.
- Share college: Share of persons over 25 with 4 or more years of college. 1970-2000. Corresponding shares of college graduates (completed at least 16 years of school) from 1940 and 1950 from the full count population Census are used as the base. Source: Census Bureau (2023a) and Ruggles et al. (2024).
- Employment in education: Labor force employed in educational services. 1960 and 1970. Corresponding numbers of educational services (“888” in IND1950) from 1940 and 1950 from the full population census are used as the base. Source: Census Bureau (2023a) and Ruggles et al. (2024).
- Education spending: Local government’s total general expenditure, multiplied by local government’s percentage spending on education. 1957, 1962, 1967, 1972, 1977, and 1982. Source: HDES.

Public sector

- Federal government employment: Federal government: employment. 1962, 1970, 1975, 1981, 1984, 1990, and 2000. Source: HDES.
- Local government employment: Local governments: employees (full-time equivalent). 1962, 1967, 1972, 1977, 1982, 1990, and 2000. Source: HDES.
- Local government annual payroll: Local governments: payroll. 1962, 1967, 1972, and 1977. Source: HDES.

B.2 County characteristics (control variables)

- Time-invariant characteristics: land area, longitude, latitude, and 1940 values of log population. Source: HDES.
- 1940 agriculture conditions: share of sharecroppers, total farm acres, shares of farms in five farm-size bins (1 to 9 acres, 10 to 49 acres, 50 to 99 acres, 100 to 499 acres, 500 to 999 acres, and 1000 acres and more), and acres harvested in cotton, tobacco, corn, and hay, respectively. Source: Agriculture Census.
- New Deal variables: Per capital values of federal grants on public work (“pcpubwor”) and the payments to farmers through the Agricultural Adjustment Administration (“pcaaa”). Source: Fishback et al. (2005).
- Trade exposure: Japanese trade exposure during the 1970s and 1980s (“d_ipw”). The variable is constructed using industry employment share within manufacturing, and it measures the change in import exposure faced by the average worker. Source: Batistich and Bond (2023).

C Quantitative Framework Appendix

C.1 Initial equilibrium

Before performing the counterfactual analysis, I first construct bilateral trade flows between all regional pairs using the market access term approach (Donaldson and Hornbeck, 2016; Allen and Donaldson, 2022). The bilateral trade flows between importer n and exporter i in industry k can be

expressed as a function of trade costs $\tau_{ni,t}^s$, price index $P_{n,t}^s$, expenditure $X_{n,t}^s$, and total income $Y_{n,t}$, with productivity $A_{i,t}^s$ and distance elasticity θ^k :

$$\begin{aligned} X_{ni,t}^s &= \left(\tau_{ni,t}^s \frac{w_{i,t}^s}{A_{i,t}^s} \right)^{-\theta^k} (P_{n,t}^s)^{\theta^k} \times \varphi^k Y_{n,t} \\ &= T_{ni,t}^s \times \left(\frac{Y_{i,t}^s / Y_W}{(\Pi_{i,t}^s)^{-\theta^k}} \right) \times \left(\frac{X_{n,t}^k / Y_W}{(P_{n,t}^s)^{-\theta^k}} \right). \end{aligned} \quad (\text{OA16})$$

World income Y_W normalizes the output and expenditure. The second line follows from introducing the outward market access term $\Pi_{i,t}^s \equiv \left(\frac{w_{i,t}^s}{A_{i,t}^s} \right)^{-1} \left(\frac{Y_{i,t}^s}{Y_W} \right)$ and the effective trade costs $T_{ni,t}^s = (\tau_{ni,t}^s)^{-\theta^k}$.

The outward market access term $\Pi_{i,t}^s$ captures how close exporter i is to the potential importers. The price index $P_{n,t}$ represents the inward trade market access and captures how close each importer n is to exporters. Using the two market access terms, the following proposition defines the initial equilibrium for trade.

Proposition 1 (Initial Equilibrium). Given the allocation labor, $\{L_t\}$, trade costs raised to elasticity exponent, $\{T_t\}$, and consumption share, $\{\varphi^k\}$, the solution to the initial equilibrium at t is the set of market access terms and wages, $\{P_t, \Pi_t, w_t\}$. In particular, it is obtained as the solution to the following system of non-linear equations:

Outward and Inward Trade Market Access Terms:

$$(\Pi_{i,t}^k)^{-\theta^s} = \sum_{j=1}^N T_{ji,t}^s \times X_{j,t}^s \times (P_{j,t}^k)^{\theta^s}, \quad (\text{I1a})$$

$$(P_{n,t}^k)^{-\theta^s} = \sum_{j=1}^N T_{nj,t}^s \times Y_{j,t}^k \times (\Pi_{j,t}^k)^{\theta^s}. \quad (\text{I1b})$$

Trade Flows:

$$X_{ni,t}^k = T_{ni,t}^k \times \frac{Y_{i,t}^k}{(\Pi_{i,t}^k)^{-\theta^s}} \times \frac{X_{n,t}^s}{(P_{n,t}^k)^{-\theta^s}}. \quad (\text{I2})$$

Output and Expenditure:

$$Y_{n,t}^s = w_{n,t}^s L_{n,t}^s, \quad Y_{n,t} = \sum_k Y_{n,t}^k, \quad \text{and} \quad X_{n,t}^k = \varphi^s Y_{n,t}^s. \quad (\text{I3})$$

Wages:

$$w_{n,t}^s L_{n,t}^s = \sum_{j=1}^N X_{jn,t}^s. \quad (\text{I4})$$

where I iterate Equations (I1a) to (I4) using wages with labor as the only factor of production. It is equivalent to assuming that capital perfectly adjusts to labor in each period. I adopt this

simplification for the purpose of calculating trade share, and the resulting wages are only used to construct the market access terms and not used outside the Initial Equilibrium.

C.2 Dynamic Exact Hat Algebra

I adopt the dynamic hat algebra approach of Caliendo et al. (2019) for the counterfactual analysis. Dynamic hat algebra calculates how allocations and prices change in a counterfactual economy relative to a baseline economy across space and time. It annihilates the need to recover time-invariant fundamentals and focuses on quantifying the changes in allocations and prices, given a new sequence of fundamentals.

First, I clarify fundamentals and prices. Geographic fundamentals $\{\bar{Z}_{i,t}^s, \bar{A}_{i,t}^{w,s}, \bar{A}_{i,t}^{k,s}, B_{i,t}, \tau_{ni,t}^s, \kappa_{ni,t}\}$ consists of fundamental productivity of firm, $\bar{Z}_{i,t}^s$; fundamental efficiency of labor and capital, $\bar{A}_{i,t}^{w,s}$ and $\bar{A}_{i,t}^{k,s}$; location amenities, $B_{i,t}$; and iceberg-type trade costs and migration costs, $\tau_{ni,t}^s$ and $\kappa_{ni,t}$. I use the terms Θ_t or $\bar{\Theta}$ to denote time-varying and time-constant fundamentals of the economy.

Prices and allocation $\{w_{i,t}^s, r_{i,t}^s, L_{i,t}, K_{i,t}, \mathbb{V}_{i,t}^l\}$ consists of location-sector specific factor prices: wage $w_{i,t}^s$ and rental rate of capital $r_{i,t}^s$; the measure of workers, $L_{i,t}$ and the stock of capital, $K_{i,t}$; and workers' value function, $\mathbb{V}_{i,t}^l$.

A dot notation expresses a variable in terms of changes over time: $\dot{Y}_{t+1} \equiv Y_{t+1}/Y_t$. A prime denotes the value at the counterfactual economy, and the change in the counterfactual economy can also be expressed in terms of time changes: $\dot{Y}'_{t+1} \equiv Y'_{t+1}/Y'_t$. Lastly, a hat variable, $\hat{Y}_t \equiv \dot{Y}'_t/\dot{Y}_t$, stands for the counterfactual time change relative to the baseline time changes for any variable Y .

In the baseline case, the saving rate of capitalists, $\varsigma_{n,t}$, is fixed at β using the log consumption utility, with the value of the intertemporal elasticity of substitution equalling to one ($\psi=1$). If $\psi > 1$, capitalists flexibly substitute consumption in different time periods, suggesting that the rise in the rental rate of capital induces a higher saving rate. In other words, the substitution effect dominates. However, if $0 < \psi < 1$, the income effect dominates, and the saving rate decreases with the rise in the rental rate. Furthermore, in a more general setting, the sectoral consumption share of capitalists can be allowed to vary and be determined in the Sequential Equilibrium using the shooting algorithm, as discussed in Section C.3.

For production, the variable $\xi_{i,t}^s = (w_{i,t}^s L_{i,t}^s)/(w_{i,t}^s L_{i,t}^s + r_{i,t}^s K_{i,t}^s)$ represents the cost share of labor, and $\phi_{is,t}^k$ the consumption shares of individuals in labor market i -s on sector k at time t . The factors of production are intra-temporarily reallocated across sectors until effective payments are equalized across sectors.

Proposition 2 (Temporary Equilibrium). Given the allocation of the temporary equilibrium at t , $\{L_t, K_t, X_t, \mathbb{S}_t, \phi_t\}$, the solution to the temporary equilibrium at $t+1$ for a given change in \hat{L}_{t+1} , \hat{K}_{t+1} , and $\hat{\Theta}_{t+1}$ does not require information on the level of fundamentals at t , Θ_t or $\bar{\Theta}$. In particular,

the set of solutions is obtained as the solution to the following system of non-linear equations:

$$\dot{x}_{i,t+1}^s = \left((\xi_{i,t}^s)(\dot{w}_{i,t+1}^s)^{1-\sigma^s} + (1 - \xi_{i,t}^s)(\dot{r}_{i,t+1}^s)^{1-\sigma^s} \right)^{\frac{1}{1-\sigma^s}}, \quad (\text{T1})$$

$$\dot{P}_{n,t+1}^s = \left[\sum_{i=1}^N \mathbb{S}_{ni,t}^s \left(\dot{\tau}_{ni,t+1}^s \dot{x}_{i,t+1}^s \right)^{-\theta^s} \right]^{-1/\theta^s}, \quad (\text{T2})$$

$$\mathbb{S}_{ni,t+1}^s = \mathbb{S}_{ni,t}^s \left(\frac{\dot{\tau}_{ni,t+1}^s \dot{x}_{i,t+1}^s}{\dot{P}_{n,t+1}^s} \right)^{-\theta^s}, \quad (\text{T3})$$

$$s_{i,t+1}^{w,s} = s_{i,t}^{w,s} \left(\frac{\dot{A}_{i,t+1}^{w,s} \dot{w}_{i,t+1}^s}{\dot{w}_{i,t+1}^s} \right) \quad \text{and} \quad s_{i,t+1}^{k,s} = s_{i,t}^{k,s} \left(\frac{\dot{A}_{i,t+1}^{k,s} \dot{r}_{i,t+1}^s}{\dot{r}_{i,t+1}^s} \right), \quad (\text{T4})$$

$$\dot{L}_{i,t+1}^s = \dot{A}_{i,t+1}^{w,s} s_{i,t+1}^{w,s} \dot{L}_{i,t+1} \quad \text{and} \quad \dot{K}_{i,t+1}^s = \dot{A}_{i,t+1}^{k,s} s_{i,t+1}^{k,s} \dot{K}_{i,t+1}, \quad (\text{T5})$$

$$E_{n,t+1}^s = \dot{w}_{n,t+1}^s \dot{L}_{n,t+1}^s w_{n,t}^s L_{n,t}^s \quad \text{and} \quad E_{n,t+1}^k = (1 - \beta) \sum_{s \in \{a,m,l\}} \dot{R}_{n,t+1}^s \dot{K}_{n,t+1}^s R_{n,t}^s K_{n,t}^s \quad (\text{T6})$$

$$\phi_{is,t+1}^k = \phi^k + (\phi_{is,t}^k - \phi^k) \left(\frac{\dot{w}_{i,t+1}^s}{\dot{P}_{i,t+1}^s} \right)^{-\varepsilon}, \quad (\text{T7})$$

$$\dot{Y}_{i,t+1}^s Y_{i,t}^s = \sum_{n=1}^N \mathbb{S}_{ni,t+1}^s \left(\sum_{s=1}^S \varphi_{ns,t+1}^s E_{n,t+1}^s + \varphi_{ns,t+1}^k E_{n,t+1}^k \right), \quad (\text{T8})$$

$$\dot{w}_{n,t+1}^s \dot{L}_{n,t+1}^s w_{n,t}^s L_{n,t}^s = \xi_{i,t+1}^s \dot{Y}_{i,t+1}^s Y_{i,t}^s \quad \text{and} \quad \dot{r}_{n,t+1}^s \dot{K}_{n,t+1}^s r_{n,t}^s K_{n,t}^s = (1 - \xi_{i,t+1}^s) \dot{Y}_{i,t+1}^s Y_{i,t}^s, \quad (\text{T9})$$

$$K_{i,t+1} = \beta \bar{R}_{i,t} K_{i,t}. \quad (\text{T10})$$

The next proposition shows how to calculate a dynamic sequence of the economy. I study how migration flows, \mathbb{M} , vary by the new sequence of temporary equilibrium. I define $\mathbb{V}_{n,t}^k \equiv \exp(V_{n,t}^k)$. **Proposition 3 (Sequential Equilibrium).** Given an initial allocation of the economy, $(L_0, K_0, X_0, \mathbb{S}_0, \varphi_0, \mu_{-1})$, and an anticipated convergent sequence of time changes in fundamentals, $\{\dot{\Theta}_t\}_{t=\tau+1}^\infty$ with $\lim_{t \rightarrow \infty} \dot{\Theta}_t = 1$, the solution to the sequential competitive equilibrium in time differences does not require information in the level of fundamentals, $\{\Theta_t\}_{t=0}^\infty$, where all agents are assumed to learn the full sequence shock between τ and $\tau + 1$. In particular, the changes in migration shares and

capital stocks are obtained as the solution to the following system of non-linear equations:

$$\mathbb{M}_{in,t+1} = \frac{\mathbb{M}_{in,t}(\dot{\mathbb{V}}_{i,t+2})^{\beta/\eta}}{\sum_{l=1}^N \mathbb{M}_{il,t}(\dot{\mathbb{V}}_{l,t+2})^{\beta/\eta}} \quad (\text{S1})$$

$$\dot{\mathbb{V}}_{n,t+1}^k = \dot{B}_{n,t+1} \dot{C}_n(\dot{L}_{t+1}, \dot{\Theta}_{t+1}) \left(\sum_{i=1}^N \sum_{s=1}^k \mathbb{M}_{ni,t}(\dot{\mathbb{V}}_{i,t+2})^{\beta/\eta} \right)^\eta, \quad (\text{S2})$$

$$L_{n,t+1} = \sum_{i=1}^N \mathbb{M}_{in,t} L_{i,t}. \quad (\text{S3})$$

where the changes consumption indirect utility, $C_n(\dot{L}_{t+1}, \dot{\Theta}_{t+1})$, is constructed from the solution of the temporary equilibrium given $\{\dot{L}_t, \dot{\Theta}_t\}_{t=1}^\infty$:

$$C_{n,t+1} = \frac{1}{\varepsilon} \left(\frac{\dot{\bar{w}}_{n,t+1}}{\dot{P}_{n,t+1}} \frac{\bar{w}_{n,t}}{P_{n,t}} \right)^\varepsilon - \sum_{s=1}^k v^s \ln \dot{P}_{n,t+1}^s P_{n,t}^s.$$

I first recover wages at $t = 1$ consistent with the initial period economic allocation. The first term in RHS is the real wage component and the second term is the non-homothetic price adjustments.

Stationary Equilibrium. A stationary equilibrium is a sequential competitive equilibrium such that $\{\mathbf{L}_t, \mathbb{M}_t, \mathbb{V}_t, \mathbf{w}_t, \mathbf{K}_t, \mathbf{r}_t\}_{t=0}^\infty$ is constant for every t . A stationary equilibrium in this economy is a situation in which no aggregate variables change over time. It requires fundamentals to be constant for all t . In a stationary equilibrium, individuals continually move from one market to another, but inflows and outflows balance.

C.3 Capitalists' problem with non-homothetic preference

This section extends the baseline model by introducing the PIGL preference to capitalists. As in the baseline model, capitalists of measure one in each location choose their consumption and investment to maximize the expected present discounted value of their flow consumption utility:

$$v_{i,t}^k = \mathbf{E}_t \sum_{t=0}^{\infty} \beta^t C(E_{i,t}^k, P_{i,t}), \quad (\text{OA17})$$

where now the consumption utility is defined the same as workers. Note that they are assumed to be geographically immobile, and local amenity terms are ignored. They choose the path of consumption expenditure and regional capital, $\{E_{i,t}^k, K_{i,t+1}\}_{t=0}^\infty$, subject to their budget constraint:

$$\bar{r}_{i,t} K_{i,t} = E_{i,t}^k + P_{i,t} (K_{i,t+1} - (1 - \delta) K_{i,t}), \quad (\text{OA18})$$

where $\bar{r}_{i,t}$ is the average net return on capital. The gross return on capital can be written as $\bar{R}_{i,t} \equiv 1 - \delta + \bar{r}_{i,t}/P_{i,t}$ with the depreciation rate δ . The capital is geographically immobile once installed and depreciates gradually at a constant rate δ . The investment goods combine goods from all sectors with the asymptotic consumption share.

The augmented capitalists' problem can be separated into the intratemporal problem of allocating consumption expenditure across sectors and intertemporal investment decisions. The solution to the intratemporal problem follows the same structure as workers given expenditure $E_{i,t}^k$. The intertemporal problem maximizes the intertemporal utility subject to the budget constraint. The resulting Euler equation is given as:

$$\left(\frac{E_{i,t+1}^k/P_{i,t+1}}{E_{i,t}^k/P_{i,t}} \right)^{1-\varepsilon} = \beta \mathbf{E}_t[1 - \delta + \bar{r}_{i,t+1}/P_{i,t+1}] = \beta \mathbf{E}_t[\bar{R}_{i,t+1}], \quad (\text{OA19})$$

which, along with the transversality condition, governs the dynamic conditions of capitalists.

In each region, transition paths of capital and expenditure are determined by a shooting algorithm with initial values of capital and initial guesses of expenditure. Given the rental rate of capital determined in temporary equilibrium, I construct the flow of capital and expenditure with the Euler equation and capitalists' budget constraint. If the obtained path for capital converges to the steady state, the algorithm is terminated; otherwise, the guess on initial expenditure is updated.

For the model calculation, Equation T10 in the sequential equilibrium is changed to:

$$(\dot{E}_{i,t+1}^k/\dot{P}_{i,t+1})^{1-\varepsilon} = \beta \mathbf{E}_t[1 - \delta + (\dot{\bar{r}}_{i,t+1}\bar{r}_{i,t})/(\dot{P}_{i,t+1}^s P_{i,t}^s)] \quad \text{and} \quad K_{i,t+1} = I_{i,t+1}^k - E_{i,t+1}^k + \delta K_{i,t}.$$

D Additional Empirical Results

D.1 Instrument validity check

In addition to statistical tests discussed in the main text, I introduce various placebo tests (Tables OA3 to OA5), falsification tests in terms of outcomes (Table OA2), and an additional overidentification tests using two migration exposures by race (Table OA6).

First, I document placebo tests in terms of treatment (Table OA3), share (Table OA4), and shift (Table OA5). For the placebo treatment, I randomly switch the northern exposure, the main regressor, across the southern counties. For the share, I randomly reallocate the migration cell when constructing the migration exposure in the shift-share design. For the shift, I assign a random number of immigrants in the North and reallocate them back to the South. The placebo experiments lead to statistically insignificant estimates, with their signs and magnitudes not systematically re-

lated to the main estimates.

Table OA2 presents falsification tests using public employment and payroll as dependent variables. The simple framework highlights the private industries' adjustments to the change in relative factor abundance. On the contrary, the public sector would not have been much affected by such a change. Indeed, the public sector did not respond in terms of employment and annual payroll (Columns 1 to 3). Local government employment even may have slightly decreased (Column 2). The results also suggest that the empirical results on non-agricultural development are not likely to be driven by government policies.

Table OA6 tests whether out-migration from Black and White led to similar changes in the economic outcomes. Tables OA11 and OA12 further report the results separately for migration exposures to either Blacks or Whites. While there is no systematic difference between the impacts from Black and White out-migration (Table OA6), the estimates tend to be less precisely estimated for the Black out-migration compared to White (Tables OA11 and OA12).

D.2 Robustness check

Tables OA7 to OA21 estimate the main results using alternative empirical strategies and document how the results affected in each case. First, Table OA1 replicates the main outcomes in Tables 2 and 3, Panel D, and Table 4, Panels A and B for comparison. Then, I document the following robustness checks: (1) adopting alternative approaches for in-migration prediction (by using actual in-migration rates in Table OA7 or by using random forest prediction method in Table OA8), (2) the alternative share based on 1935-1940 migration matrix using 1935 locations in the 1940 Census (Table OA9), (3) separately estimating by race (Tables OA11 and OA12), (4) limiting the sample to former confederate states (Table OA13), (5) limiting the North-South migration linkages only for the seven major destination cities (Table OA10), (6) dropping the time-varying controls (contemporaneous population and net migration rate, Table OA14), (7) dropping the predicted out-migration controls (three decadal rates separately for Blacks and Whites, Table OA15), (8) limiting sample counties to be balanced for all variables (Table OA20), (9) using 1940 population-weighted regression (Table OA21), and (10) including 1960 in base years (1940, 1950, and 1960, Table OA18) or dropping 1950 as the base year (Table OA19)).

Finally, I create additional time-interacted controls that can at least partially take into account potentially correlated migration exposure across Southern counties. I do so by calculating the weighted average of the Northern migration exposures, the excluded instrument. First, I calculate the average of adjacent counties' migration exposure, where the weight is proportional to the squared inverse distance, as in Greenland et al. (2019) (Table OA16). Alternatively, I use pre-period migration linkages within the South during the 1910-1940 period as weights, as in Borusyak

et al. (2023) (Table OA17).

I mainly discuss the cases when the results differ from the baseline results. Table OA9 reports the estimates using the alternative migration share between 1935 and 1940. As demonstrated using overidentification tests documented in Table OA4, the baseline migration share and the alternative 1935-1940 share tend to produce similar results. However, there are notable differences for manufacturing value-added, with a slightly negative estimate, and for retail variables, which are less precisely estimated. The difference between the baseline method and the 1935-1940 migration matrix may be due to more sparse migration cells in the 1935-1940 share. As pointed out in the main text, the Census Tree approach generates 1,748,472 (18.2%) non-zero migration cells among all possible flows, while the 1940 Census approach between 1935 and 1940 generates 830,892 (8.6%) non-zero cells. Nonetheless, the main messages of the paper are maintained when both migration shares are used together (Table A4)

Table OA15 drops the predicted out-migration rates, which are used as proxies for Southern push factors. The estimated coefficients tend to be similar in magnitude and statistical significance. However, the first-stage F-statistics tended to be 10% to 20% higher without the controls. This pattern would arise due to the reduced predictive power of Northern exposure in predicting out-migration rates, where the predicted rates also capture the variations in actual out-migration to a certain degree. Still, the similar reduced-form results with or without the control variable offer credibility of the excluded instrument in proxying the Northern pull factors. Note that the first stage's predictive power does not directly influence the reduced-form estimates, which are the main focus of the empirical section.

Tables OA18 and OA19 report the estimates using alternative base years. The former includes all values during the Second Great Migration periods (1940, 1950, and 1960) as the base, while the latter only uses the value at the start of migration (1940) as the base. Note that the baseline analysis uses 1940 and 1950 outcomes as the base. The rationale for the choice is that 1960 outcomes are expected to contain the influences from the migration flows during the earlier period between 1940 and 1960. Still, the 1950 values are included to minimize the influences of using a single year (1940). The patterns in Tables OA18 and OA19 support this view. They show that including the later year in the base tends to reduce the size of the coefficients. In contrast, using the 1940 values as the sole base tends to increase the overall size of the coefficients but at the cost of less precise estimates for some variables.³

The results are similar in the other scenarios: adopting alternative approaches for in-migration prediction, limiting the sample to former confederate states, using 1940 population-weighted regression, and including 1960 in base years (1940, 1950, and 1960), and limiting sample counties

³For instance, the standard errors in agriculture (Panel A, Column 1) and manufacturing employment (Panel B, Column 1) tended to increase by 13% and 24%, compared to the baseline estimates (Table OA1).

to be balanced for all variables. Tables OA16 and OA17 show that adding the weighted average of Northern exposures within the South does not affect the results in a systematic way.

E Additional Tables and Figures

Figure OA1: Scatter plot of the First-Stage using the alternative share (1935-1940).

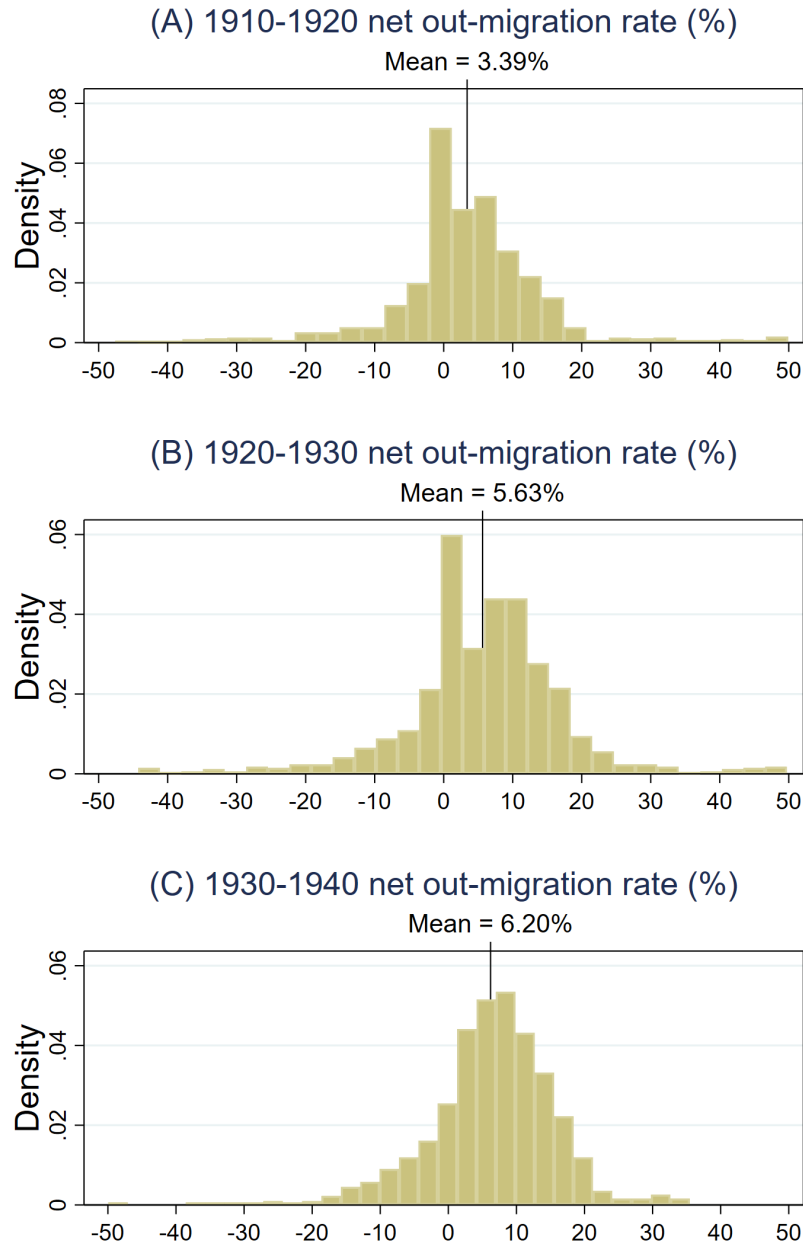

Note: The figure presents first-stage regression results using an alternative migration exposure constructed from the 1935-1940 migration matrix from the 1940 Census record Ruggles et al. (2024). The y-axis plots the net migration rates between 1940 and 1970 in Southern counties, and the x-axis is the migration exposure measure for the years between 1940 and 1970, constructed by the SSIV strategy described in the main text. The net migration rates are from Gardner and Cohen (1992) and Bowles et al. (2016). Both the left-hand- and right-hand-side variables have been residualized by the set of control variables described in the main text and state fixed effects.

Figure OA2: Distribution of the average decadal net migration rate (1940-1970).

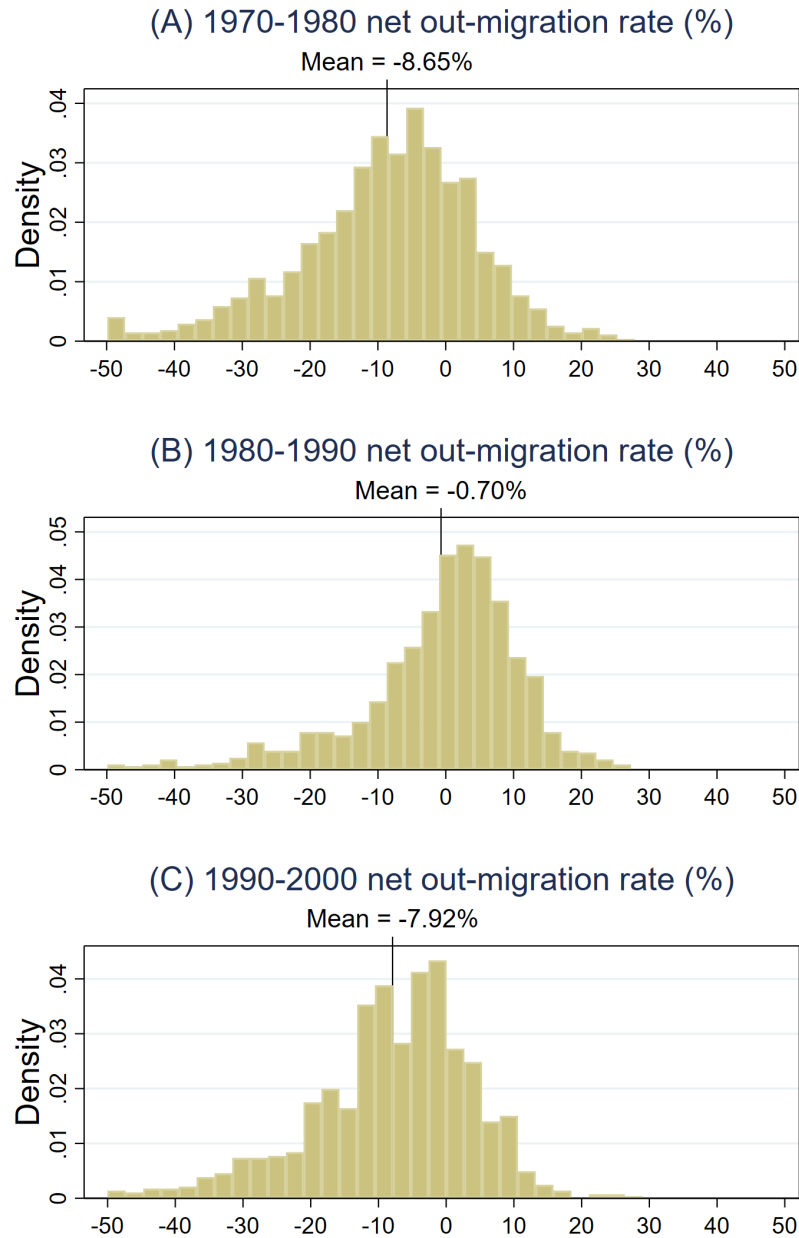

Note: The figure plots the distribution of county-level, out-of-county, net out-migration rates among the sample Southern counties. Panels A to C show decadal-level values for the “treatment period” of the Second Great Migration (1940-1970). The straight vertical line shows the average value in each decade. Outliers with more than 50% or less than -50% net out-migration rates are dropped from the histograms.

Figure OA3: Distribution of the average decadal net migration rate, pre-period (1910-1940).

Note: The figure plots the distribution of county-level, out-of-county, net out-migration rates among the sample Southern counties. Panels A to C show decadal-level values for the “pre-period” before the Second Great Migration (1910-1940). The straight vertical line shows the average value in each decade. Outliers with more than 50% or less than -50% net out-migration rates are dropped from the histograms.

Figure OA4: Distribution of the average decadal net migration rate, post-period (1970-2000).

Note: The figure plots the distribution of county-level, out-of-county, net out-migration rates among the sample Southern counties. Panels A to C show decadal-level values for the “post-period” after the Second Great Migration (1970-2000). The straight vertical line shows the average value in each decade. Outliers with more than 50% or less than -50% net out-migration rates are dropped from the histograms.

R-squared	0.269	0.435	0.141	0.129	0.659	0.727	0.679	0.623
First-stage F	0.35	0.37	0.36	0.16	0.38	0.39	0.39	0.38
Counties	1,083	1,096	1,086	1,086	1,096	1,096	1,096	1,096

Note: The table reports reduced-form estimates from Equation (4) using randomly shuffled Northern exposure as the excluded instrument. Panels A to C correspond to the baseline results in Tables 2 to 4 with the full set of fixed effects and control variables. Each column reports the changes in the indicated outcome variable in logs for the years 1970 to 2010 by standardized Northern migration exposure, relative to the omitted years of 1940 and 1950. Robust standard errors are clustered by county and reported in parentheses, and the first-stage Kleibergen-Paap robust F-statistics are reported. Stars represent: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

Table OA4: Placebo test - Random share.

Counties	1,083	1,096	1,086	1,086	1,096	1,096	1,096	1,096

Note: The table reports reduced-form estimates from Equation (4) with an alternative migration exposure created by only using counties in the Seven major Northern destination cities (based on “Labor Market Area”) during the 1940-1970 periods. They include: New York-Nassau-Suffolk, NY (19400), Chicago, IL (24300), Los Angeles-Long Beach, CA (38300), Philadelphia, PA-NJ-Vineland-Millville-Bridgeton, NJ (19700), Detroit-Flint, MI (11600), St. Louis, MO-IL (24701 + 24702), and Pittsburgh, PA (19700). Panels A to C correspond to the baseline results in Tables 2 to 4 with the full set of fixed effects and control variables. Each column reports the changes in the indicated outcome variable in logs for the years 1970 to 2010 by standardized Northern migration exposure, relative to the omitted years of 1940 and 1950. Robust standard errors are clustered by county and reported in parentheses, and the first-stage Kleibergen-Paap robust F-statistics are reported. Stars represent: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

Counties	1,083	1,096	1,086	1,086	1,096	1,096	1,096	1,096

Note: The table reports reduced-form estimates from Equation (4) by adding time interacted values of the weighted average of Southern counties' Northern migration exposures as additional control variables. The weight is proportional to the pre-period (1910-1940) migration linkages within the South, as in Borusyak et al. (2023). The migration linkages are based on the matched Census files Buckles et al. (2023); Ruggles et al. (2024). Panels A to C correspond to the baseline results in Tables 2 to 4 with the full set of fixed effects and control variables. Each column reports the changes in the indicated outcome variable in logs for the years 1970 to 2010 by standardized Northern migration exposure, relative to the omitted years of 1940 and 1950. Robust standard errors are clustered by county and reported in parentheses, and the first-stage Kleibergen-Paap robust F-statistics are reported. Stars represent: * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$.

Table OA18: Robustness - Base year extension (1940, 1950, and 1960).
